The objective of the study was to evaluate the efficacy of misoprostol in patients with complication of first trimester pregnancy loss. After the departmental approval, a total of 102 women with first trimester pregnancy failure were recruited for treatment with misoprostol. The inclusion criteria were gestational age of less than 12 weeks and hemodynamically stable. The exclusion criteria were patients with history of hypersensitivity to prostaglandin, bronchial asthma and hemoglobin less than 9 g. Main outcome measures were the successful resolution of miscarriages without surgical intervention; secondary outcomes were incidence of pain, vaginal bleeding, infection, pyrexia and gastrointestinal side effects. A total of 102 women were included in the study. Age ranged from 16 to 40 years and parity ranged from 0 to grand multipara. Women were not selected according to parity but parity was a random occurrence. No relationship was found between parity and response to treatment with misoprostol. Incomplete abortion was found in 82 (80.39%), an embryonic pregnancy in 7 (6.86%) and early fetal demise in 13 (12.74%). 62.74% women completely expelled the conceptual products on treatment with misoprostol alone, while 38 (37.25 %) patients required surgical evacuation due to incomplete expulsion of conceptual products. Mean induction to expulsion interval was 15.66 h. Main side effects noted were pain, pyrexia, nausea, vomiting and diarrhea. More than one side effect was noted in 7 (22.54%) patients. Treatment of early pregnancy loss with misoprostol is efficient, acceptable and cost effective for patients with complications of first trimester pregnancy loss.

Key words: Misoprostol, medical treatment, miscarriage.

INTRODUCTION

Post abortion care refers to the services required by women who have problems after pregnancy failure. Treatment is recommended in first trimester pregnancy loss to reduce morbidity like pelvic inflammatory disease (PID), hemorrhage, blood coagulation defects, and chronic pelvic pain in fertility. Medically, pregnancy loss is usually described as “incomplete” or “missed” abortion. An “incomplete abortion” is usually diagnosed when the

A woman has an open cervix and has passed some, but not all the products of conception. A “missed abortion” is diagnosed when a woman has a closed cervix, a uterus which does not increase in size and a non-viable embryo or fetus (an embryonic pregnancy or an embryonic/fetal demise). Terminology is embryo (0 to 8 weeks) and fetus (9 to 12 weeks).

There are different treatment options available for treatment of early pregnancy loss; the choice lies between expectant, surgical and medical treatment (Khan et al., 2007; Alberman, 1992; Macrow and Elstein, 1993). Expectant management is to wait for spontaneous abortion, but the success rate with the use of this approach for embryonic or fetal death or anembryonic gestation is suboptimal (ranging from 25 to 76%). The interval to spontaneous expulsion is unpredictable, and it may take a month. The uncertainty and anxiety, along with the sadness resulting from pregnancy loss, often make expectant management less appealing to patients (Ballagh et al., 1998; Jurkovic et al., 1998).

Surgical evacuation was the treatment of choice before medical treatment was used, but due to increased morbidity associated with surgical procedure, studies are ongoing to determine the efficacy and safety of medical treatment (Khan et al., 2007). Prostaglandins have emerged as the agents of choice for medical treatment of first trimester pregnancy loss.

Several studies have shown that medical treatment is a safe, effective and acceptable alternative to suction curettage. Misoprostol (15 deoxy-16 hydroxy 16 methyl PGE1) is a stable, synthetic form of prostaglandin E1 analogue. It was originally developed in 1970’s for the prevention of non-steroidal anti-inflammatory drugs (NSAID) induced peptic ulcers (Luise et al., 2002; Mazhar et al., 2013; Awan et al., 2008). Several clinical trials have evaluated the use of misoprostol alone for termination of early pregnancy failure (Bogratee et al., 2014; Beucher et al., 2003).

In the last two decades, medical termination of pregnancy has become a safe alternative to vacuum aspiration and dilatation and curettage (Blanchard et al., 2005; Borgatta et al., 2004; Creinin and Damry, 1993). The cost savings to the patient and family is extremely important, even if the misoprostol administration did not lead to uterine evacuation. It would soften the cervix and make surgical evacuation an easier procedure.

The objective was to study the efficacy of misoprostol in women with complication of first trimester pregnancy loss as this is cost effective for low resource population. Misoprostol has long been used in our country, but there are few studies regarding its use as abortifacient.

RESULTS

A total of 102 women were included in the study. Age range from 16 to 40 years and parity ranged from 0 to grand multipara (Table 1). Women were not selected according to parity but parity was a random occurrence. No relationship was found between parity and response to treatment with misoprostol (Table 2).

Incomplete abortion was found in 82 (80.39%), an embryonic pregnancy in 7 (6.86%) and early fetal demise in 13 (12.74%). Sixty four (62.74%) patients completely expelled the conceptual products on treatment with misoprostol alone, while 88 patients (37.25%) required a second dose of 800 mcg with advice for follow up on seventh day if the products of conception were still not completely expelled. The medical treatment was considered unsuccessful and a surgical evacuation was performed. Vital signs of vaginal bleeding and abdominal pain were assessed and adverse effects were recorded. Induction to expulsion interval was defined as the time in hours from initiation of therapy until the expulsion of products of conception. All data were collected in a predesigned proforma and were analyzed on SPSS version 16.0

DISCUSSION

Termination of pregnancy for various reasons is a common obstetrical problem. Induction of abortion needs meticulous and effective care. The rate of maternal mortality and morbidity increases significantly by surgical
It was found that treatment with low dose regimens, that is, dose of 200 to 400 µg every 4 to 6 h were associated with less successful outcome as compared to our regimens of 800 mcg misoprostol. Szymarska et al. (2003) reported 30.0% success rate with the use of 400 µg of vaginal misoprostol and this success variation may be due to this reason. Differences in initial dosage, time interval during administrations, method and routes of drug administration, population and criteria for diagnosis of incomplete abortion were suggested to be relevant in explaining differences in outcome (Graziosi et al., 2004; Jain et al., 2002, 2001).

In our study, vaginal route was used for administration of misoprostol. Vaginal route appears to be the most effective, followed by sublingual with oral being the least effective. Sublingual misoprostol needs a more frequent administration, that is, every 3 h to achieve a similar effectiveness to the vaginal route (Kooper and Mishell, 1996; Kovavisiarach and Jamnansiri, 2005; Mailre et al., 2000; Behrashi and Mahdian, 2009).

Incidence of pyrexia (5.88%), nausea (13.72%), vomiting (5.88%), diarrhoea (0.98%), and heavy vaginal bleeding (22.54%), respectively. This is comparable to the study conducted by Mazhar et al. (2013). Oral and sublingual administration of misoprostol is associated with more gastrointestinal side effects than vaginal route. Abdominal pain was noted in 54.9% of women. It was much high in comparison to other studies (Wood and Brain, 2002; Neilson et al., 1999). The incidence of heavy vaginal bleeding >500 ml was 22.54%. It was in contrast with the study conducted by Khan F.M when only 6.2% patient had heavy vaginal bleeding. None of the patient had pelvic inflammatory disease.

Age, parity and gestational age did not affect success route of medical abortion using misoprostol. Similar observation was noted in other studies (Neilson et al., 1999; Zhang et al., 2005).
